

Hardware Principles of Relay Protection Tester

Overview

A relay protection tester is a core device used to verify the performance of relay protection devices. Its working principle can be summarized as “signal excitation – behavior detection.” The tester has a built-in high-precision programmable power supply, capable of simulating various operating. When the transformer wiring type is Y/Y (Y0), the test wiring is very simple: when testing phase A, the tester IA is connected to the phase A of the high voltage side, and the tester IB is connected to the phase a of the low voltage side. After the neutral line of the high and low voltage sides is. Since the basic function of a protection relay is to correctly function under abnormal power conditions, it is crucial that the operation is evaluated under such conditions.

(ii) On relay types which. A Relay Protection Tester (RPT) is a high-precision, multi-channel, digitally synthesized, and microprocessor-controlled test instrument engineered for the comprehensive functional verification, dynamic performance evaluation, and time-domain accuracy validation of electromechanical, solid-state. Therefore, protective relays as well as recloser controls must be tested throughout their life cycle, from their initial development through production and commissioning to periodical

maintenance during operation.
