

How to read the parameter table of a fiber optic splitter

Overview

This guide focuses on two critical aspects of optical splitters that define FTTH performance: split ratios (how signals are divided) and splitting architectures (how splitters are deployed). By dividing a single optical signal from a central Optical Line Terminal (OLT) into multiple outputs for Optical Network Terminals (ONTs) at users' homes, splitters eliminate the need for dedicated fibers to each residence—slashing infrastructure costs while scaling network reach. This guide. The splitter ratio in fiber optic networks refers to how optical power is distributed among the output ports of an optical splitter. Its single-fiber bidirectional transmission mechanism employs WDM, where downstream traffic adopts broadcast mode (1490nm wavelength), and upstream traffic uses TDMA. The performance of a fiber optic splitter is determined by several parameters. in Watts - W), the loss value in dB is calculated by the formula: $\text{Loss (dB)} = 10 \lg (mW1 / mW2)$ When both gains are equal, the loss is 0 dB, so there is no loss (doesn't happen obviously). If we operate with absolute gains measured in relation to 1.
